

Open it. Start when ready.

Windows 10/11, 64-bit. No coding setup is needed to run the collector.

- 1. Extract the download.** Right-click the ZIP and choose **Extract All**. Open the extracted NoseCalibration folder. Keep its files together.
- 2. Open NoseCalibration.exe.** You do not need Python, .NET, or developer tools. The optional Install.ps1 creates a Start menu shortcut; running the EXE directly is enough.
- 3. Read the notice and start.** Check the consent box, then choose **Start session**. Recording is off until you do this. Maximize the window for more room.

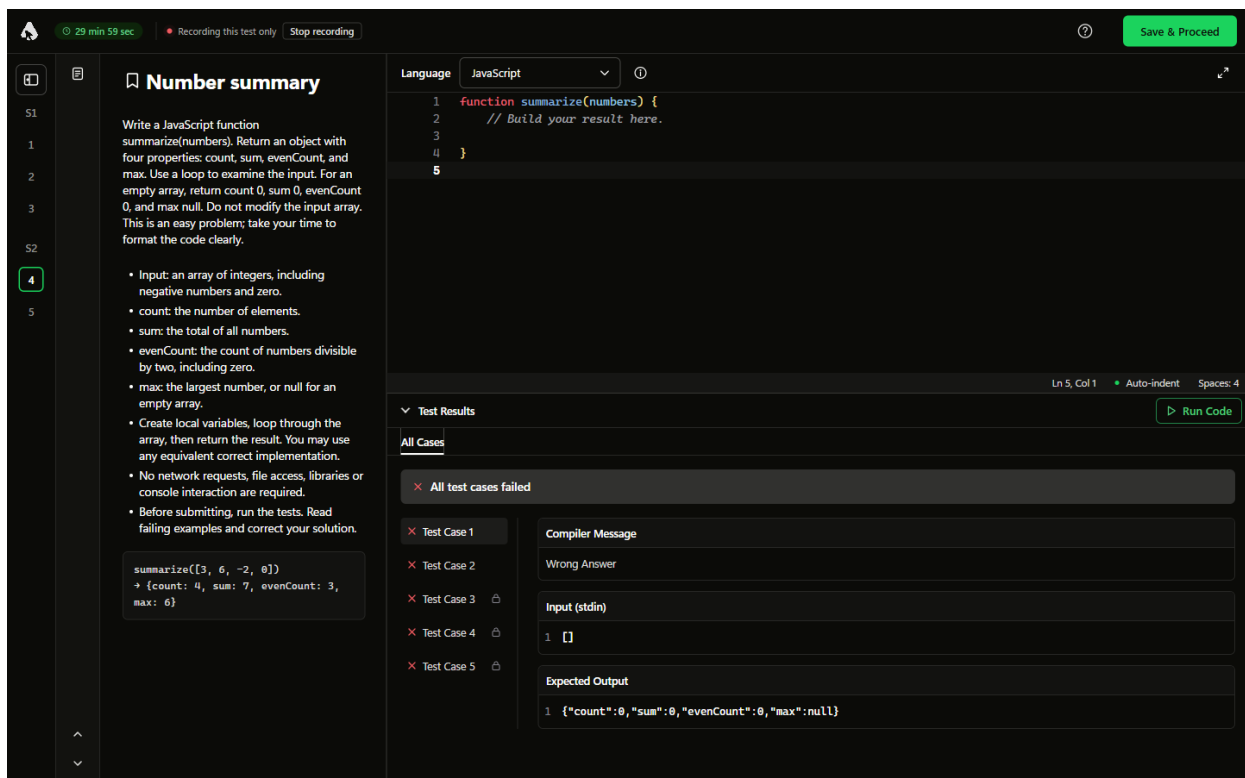

The question overview. Choose **Solve** to open a question. The top bar shows when recording is active and includes **Stop recording**.

Take the practice test.

Work naturally. For human calibration, your interaction patterns matter more than your score.

4. Answer the questions. There are multiple-choice, fill-in-the-blank and dropdown questions, plus two JavaScript coding tasks. Read, scroll, type and correct your answers as you normally would.

5. Try your code. Use **Run Code** to see results. **Save & Proceed** moves on; switching questions retains answers. You can leave a question unanswered.

6. Finish or stop. Choose **Submit Test** to grade answers and stop recording. You can instead choose **Stop recording** at any time. Closing the app also stops it. Results are saved locally.

What is recorded? Only interactions in the focused practice interface: mouse movement/clicks, keyboard events, scrolling, selections, final answers and click-triggered page screenshots. Screenshots are throttled and capped. Do not type passwords or personal information into the practice answers.

Set up sharing once.

Optional GitHub sharing uses one private repository. Finish these steps on GitHub.

On Results, the three setup buttons open GitHub pages. They do not create a repository, install the app or invite anyone for you.

- 1. Create repository.** In your personal account, create **nose-calibration-submissions** and choose **Private**. Reuse it for later recordings.
- 2. Install app.** Install **Nose Calibration**. Choose **Only select repositories** and select only **nose-calibration-submissions**. Never choose All repositories. Check for **Contents: read and write** and **Metadata: read-only**.
- 3. Open my repositories.** Open that repository, then **Settings > Collaborators > Add people**. Invite **Dhruvsa1** once; the organizer must accept. Add no other collaborators: they block sharing.

Set up once per GitHub account

Already done? Go to step 4 ^

Each button opens github.com in your browser. This app creates, installs and invites nothing by itself.

1

Create a private repository
In your personal account, name it exactly **nose-calibration-submissions** and choose **Private**.
One repository holds every recording you share.

Create repository ↗

2

Install the Nose Calibration app on that repository only
Choose **Only select repositories**, then pick **nose-calibration-submissions**.
Never choose All repositories, even if GitHub selects it first.

Install app ↗

3

Invite the organizer, once
Open **nose-calibration-submissions**, then **Settings > Collaborators > Add people** and add **Dhruvsa1**. The organizer must accept. Add no one else: other collaborators block sharing.

Open my repositories ↗

Standing access: the organizer can decrypt shared recordings and keeps write access to this inbox, including future shared sessions, until you remove them. They can read, change or delete repository files. This narrows access; it does not make sharing risk-free.

Each recording: two steps.

Already set up GitHub? Sign in if needed, then consent and share.

1. Sign in to GitHub. Enter only the code shown by this collector at github.com/login/device, authorize Nose Calibration and check the displayed account. Never enter a code someone sends you. Signing in alone uploads nothing.

2. Consent, then Encrypt and share. Read the notice and wait for the result. Numeric metrics may receive Codex advisory review; raw code, key presses and screenshots are not automatically sent to a model.

The screenshot shows a dark-themed interface titled "Each recording". It contains two numbered steps:

- Step 4: Sign in to GitHub**

This app has its own sign-in and does not use other GitHub logins on this computer. Enter the code it shows at github.com/login/device. **Only enter a code this app displays**, never one someone sends you. Then check the account name below.

Below the text is a button labeled "Sign in to GitHub". To the right of the button, there is a green dot followed by the text "Signed in to GitHub as synthetic-participant" and a "Sign out" link.
- Step 5: Consent, then encrypt and share**

Numeric metrics derived from your session may be reviewed by OpenAI Codex. Raw code, key presses and screenshots are not automatically sent to any AI model.

Below this text is a green-bordered box containing a green checkmark icon and the text: "I consent to encrypt this session on this computer, store it in my private `nose-calibration-submissions` repository, and let the study organizer keep write access to that one repository until I remove them."

Below the consent box is a green button labeled "Encrypt and share".

At the bottom of the step, there is a small text note: "A receipt appears below only after the upload is verified and the organizer's access is confirmed. If the organizer has not accepted yet, you see a pending notice instead; sharing again later only rechecks access and never uploads twice."

Stored is not yet a receipt. Encrypted data may be uploaded while organizer access is unconfirmed. The app cannot see pending invitations. Wait for acceptance, then share again to verify. A final receipt requires verified organizer access.

Sign out or revoke. The token stays in memory for at most eight hours; refresh tokens are discarded. Sign out or closing clears it locally, but does not revoke the grant. Use GitHub **Settings > Applications > Authorized GitHub Apps** to revoke Nose Calibration; use **Installed GitHub Apps** to manage its repository access. Remove Dhruvsa1 separately in repository settings. These actions do not erase copies already received.

Return later. Skip sharing to keep the recording local. **Earlier recordings** opens a saved session for retry without restarting capture. **Export session file** creates a readable ZIP: share it deliberately.

Development preview: selected-repository live authorization/upload and clean-machine installation remain unverified. If setup fails, contact the organizer; never post codes, tokens or recordings publicly. This preview is unsigned: verify unexpected Windows warnings with the organizer.
